#### (57) **ABSTRACT**

Overmolded electrical plugs with integrated strain relief are disclosed. The strain relief may have multiple protrusions extending through the overmolded housing which are visible to users. The strain relief may employ a ratcheting mechanism which permanently secures the strain relief on the electrical power cord. The strain relief may be partially assembled in a pre-lock configuration on the electrical power cord where the strain relief may be positioned on the power cord, and then be further pressed to a locked configuration in which the is securely attached to the power cord. The strain relief is self-aligned on the electrical plug during an assembly process.

# **ELECTRICAL PLUGS WITH INTEGRATED STRAIN RELIEF AND METHOD OF MANUFACTURE**

## **BACKGROUND OF THE INVENTION**

### **1. Field of the Invention**

The present invention relates in general to electrical plugs and a method of manufacture thereof. More particularly, the invention is directed to electrical plugs having integrated strain relief and the method of manufacture thereof.

### **2. Description of the Related Art**

Electrical plugs are commonly used in many commercial and residential applications. Many of the electrical plugs employ strain relief to prevent accidental separation of the plugs from the wires when the plugs are removed from sockets. However, many electrical plugs do not provide a visual indication of the strain relief mechanism. As such, users may not readily identify electrical plugs having integrated strain relief for heavy-duty applications.

Accordingly, a need exists to provide a visual indication of strain relief.

## **SUMMARY OF THE INVENTION**

In the first aspect, a strain relief assembly for an electrical power cord is disclosed. The strain relief assembly comprises a strain relief having an inner clamping surface and an outer surface, the inner clamping surface configured to form a passageway for surrounding and securing an electrical power cord, the outer surface having a plurality of protrusions extending radially away from the passageway. The strain relief assembly further comprises an overmold housing partially surrounding the strain relief, wherein the protrusions of the strain relief extends to or beyond the outer surface of the overmold housing.

In a first preferred embodiment, the outer surfaces of the protrusions are not covered by the overmold housing. The protrusions are preferably contoured to enable lateral positioning on an electrical power cord during the overmold process. The strain relief preferably has a pre-locked configuration and a locked configuration, wherein the strain relief in the pre-locked configuration is able to move laterally about an electrical power cord, the strain relief in the locked configuration is secured to the electrical power cord. The strain relief preferably comprises a first and a second section. The first section preferably comprises a first half-shell having one or more first set of protrusions, the first half-shell having a plurality of posts extending from the first half-shell. The second section preferably comprises a second half-shell having one or more second set of protrusions, the second section having a plurality of holes, each of the holes formed to receive and secure the corresponding post during an assembly process.

The first section preferably has one or more first set of protrusions and the first section has two pawls extending away from the first section. The second section preferably comprises a second set of protrusions, the second section having two racks of teeth, wherein each rack of teeth are configured to receive the corresponding pawl from the first section during an assembly process. The first section preferably has a first set of protrusions, the first section having a first and a second rack extending away from the first section. The second section preferably has a second set of protrusions, the second section having a third and a fourth rack extending

2

away from the second section, where the third and fourth racks are configured to receive the first and second racks during an assembly process.

The first section preferably comprises a first generally cylindrical section having a first set of protrusions and the first generally cylindrical section has two pawls extending away from the first generally cylindrical section. The second section preferably comprises a second generally cylindrical section having one or more second set of protrusions, the second generally cylindrical section having two sets of teeth, wherein each set of teeth are configured to receive the corresponding pawl from the first generally cylindrical section during an assembly process. The strain relief preferably comprises one-piece body having a first and a second section, the first section hingably connected to the second section, the first section configured to rotate relative to the second section about an axis parallel with the length of the electrical cord.

In a second aspect, a strain relief assembly for an electrical power cord comprises an electrical power cord, and a strain relief having an inner clamping surface and an outer surface, the inner clamping surface surrounding and securing the electrical power cord, the outer surface having a plurality of protrusions extending radially away from the length of the electrical power cord. The strain relief assembly further comprises an overmold housing partially surrounding the strain relief, wherein the protrusions of the strain relief extends to or beyond the outer surface of the overmold housing.

In a second preferred embodiment, the outer surfaces of the protrusions are not covered by the overmold housing. The protrusions are preferably contoured to enable lateral positioning on an electrical power cord during the overmold process. The strain relief preferably has a pre-locked configuration and a locked configuration, wherein the strain relief in the pre-locked configuration is able to move laterally about an electrical power cord, the strain relief in the locked configuration is secured to the electrical power cord. The strain relief preferably comprises a first and a second section. The first section preferably comprises a first half-shell having one or more first set of protrusions, the first half-shell having a plurality of posts extending from the first half-shell. The second section preferably comprises a second half-shell having one or more second set of protrusions, the second section having a plurality of holes, each of the holes formed to receive and secure the corresponding post during an assembly process.

In a third aspect, a strain relief assembly for an electrical power cord is disclosed. The strain relief assembly comprises a strain relief having an inner clamping surface and an outer surface, the inner clamping surface configured to form a passageway for surrounding and securing an electrical power cord, the outer surface having a plurality of protrusions extending radially away from the passageway, the strain relief having a coupling member extending away from the strain relief and configured to connect with an electrical plug inner body. The strain relief assembly further comprises an overmold housing partially surrounding the strain relief, wherein the protrusions of the strain relief extends to or beyond the outer surface of the overmold housing.

In a third preferred embodiment, the outer surfaces of the protrusions are not covered by the overmold housing. The strain relief preferably has a pre-locked configuration and a locked configuration, wherein the strain relief in the pre-locked configuration is able to move laterally about an electrical power cord, the strain relief in the locked configuration is secured to the electrical power cord. The strain relief preferably comprises one-piece body having a first and a second section, the first section hingably connected to the second

3

section, the first section configured to rotate relative to the second section about an axis parallel with the length of the electrical power cord.

In a fourth aspect, an electrical plug with integrated strain relief is disclosed. The electrical plug with integrated strain relief comprises an inner body assembly comprising a wire assembly comprising an electrical power cord and at least two electrical connectors, and an inner body securing and essentially surrounding the electrical connectors. The electrical plug with integrated strain relief further comprises a strain relief having an inner clamping surface and an outer surface, the inner clamping surface configured to form a passageway for surrounding and securing the electrical power cord, the outer surface having a plurality of protrusions extending radially away from the electrical power cord, and a coupling member coupling the strain relief to the inner body assembly. The electrical plug with integrated strain relief further comprises an overmolded outer housing partially encasing the inner body assembly and the strain relief, wherein the protrusions of the strain relief extend to the outer surface of the overmold housing.

In a fourth preferred embodiment, the coupling member is integral with the with the strain relief. The coupling member preferably connectably clips to the inner body assembly. The strain relief preferably has a pre-locked configuration and a locked configuration, wherein the strain relief in the pre-locked configuration is able to move laterally about the electrical power cord, the strain relief in the locked configuration is secured to the electrical power cord. The outer surfaces of the protrusions of the strain relief are preferably not covered by the overmold housing. The strain relief preferably comprises a first and a second section. The strain relief preferably comprises one-piece body having a first and a second section, the first section hingably connected to the second section, the first section configured to rotate relative to the second section about an axis parallel with the length of the electrical power cord. The inner body preferably further comprises one or more inner body protrusions projecting outward and away from the inner body, and the inner body protrusions are preferably flush with or extend beyond the overmolded outer housing. The inner body protrusions are preferably shaped to indicate an orientation.

In a fifth aspect, an electrical plug with integrated strain relief is disclosed. The plug comprises an inner body assembly comprising a wire assembly comprising an electrical power cord and at least two electrical connectors, and an inner body securing and essentially surrounding the electrical connectors. The plug further comprises a strain relief having an inner clamping surface and an outer surface, the inner clamping surface configured to form a passageway for surrounding and securing the electrical power cord, the outer surface having a plurality of protrusions extending radially away from the passageway. The plug further comprises an overmolded outer housing partially encasing the inner body assembly and the strain relief, the protrusions of the strain relief extending to the outer surface of the overmold housing, and overmolded outer housing physically couples the strain relief to the inner body assembly providing strain relief.

In a fifth preferred embodiment, the strain relief has a pre-lock configuration and a lock configuration, wherein the strain relief in the pre-lock is able to move laterally about an electrical power cord, the strain relief in the lock configuration is secured to the electrical power cord. The protrusions of the strain relief are preferably visible. The strain relief preferably comprises a first and a second section. The strain relief preferably comprises one-piece body having a first and a second section, the first section hingably connected to the

4

second section, the first section configured to rotate relative to the second section about an axis parallel with the length of the electrical power cord. The first section preferably comprises a first half-shell having one or more first set of protrusions, the first half-shell having a plurality of posts extending from the first half-shell, and the second section comprises a second half-shell having one or more second set of protrusions, the second section having a plurality of holes, each of the holes formed to receive and secure the corresponding post during an assembly process.

The first section preferably comprises a first half-shell having one or more first set of protrusions, the first half-shell having two pawls extending away from the first half-shell, and the second section comprises a second half-shell having one or more second set of protrusions, the second section having two sets of teeth, wherein each set of teeth are configured to receive the corresponding pawl from the first half-shell during an assembly process. The first section preferably comprises a first half-shell having a first set of protrusions, the first half-shell having a first and a second rack extending away from the first half-shell. The second section preferably comprises a second half-shell having a second set of protrusions, the second section having a third and a fourth rack extending away from the second half-shell, wherein the third and fourth racks are configured to receive the first and second racks during an assembly process. The inner body preferably further comprises one or more inner body protrusions projecting outward and away from the inner body, and the inner body protrusions are flush with or extend beyond the overmolded outer housing. The inner body protrusions are preferably shaped to indicate an orientation.

In a sixth aspect, an electrical plug with integrated strain relief is disclosed. The plug comprises an inner body assembly comprising a wire assembly comprising an electrical power cord and at least two electrical connectors, and a one-piece inner body securing and essentially surrounding the electrical connectors. The one-piece inner body comprises a base having one or more latching mechanisms, a first cover hingably coupled to the base on a first side of the base, and a second cover hingably coupled to the base on a second side of the base, the second side of the base opposite that of the first side of the base. The plug further comprises a strain relief having an inner clamping surface and an outer surface, the inner clamping surface configured to form a passageway for surrounding and securing the electrical power cord, the outer surface having a plurality of protrusions extending radially away from the electrical power cord. The plug further comprises an overmolded outer housing partially encasing the inner body assembly and the strain relief, wherein the protrusions of the strain relief extends to the outer surface of the overmold housing.

In a seventh aspect, a method for manufacturing an overmolded electric plug with integrated strain relief is disclosed. The method comprises producing an inner body assembly comprising a wire assembly and an inner body, the wire assembly comprising an electrical power cord and electrical connectors, the inner body securing the electrical connectors, and placing a strain relief around the electrical power cord, the strain relief having plurality of protrusions extending radially away from the electrical power cord. The method further comprises producing an injection mold comprising a top mold block, a bottom mold block, and a socket mold block, the injection mold having a mold cavity shaped to correspond to the desired shape of the overmolded electric plug with integrated strain relief, the bottom mold block shaped to receive and detachably secure the inner body assembly and a strain relief, the socket mold block having

5

socket connectors configured to receive the electrical connectors, the injection mold having a feeder injection port. The method further comprises coupling the electrical connectors to the socket connectors of the socket mold block, placing the inner body assembly and the strain relief into the bottom mold, pressing the top mold block onto the bottom mold block, injecting a molten insulating material into the injection mold through the feeder injection port, and removing the overmolded electric plug from the injection mold.

In a seventh preferred embodiment, the strain relief has an outer surface having a plurality of protrusions, and the mold cavity is shaped to receive the protrusions of the strain relief and form a seal surrounding the protrusions of the strain relief to prevent the molten insulating material from depositing on the outer surface of the protrusions of the strain relief. Placing a strain relief around the electrical power cord preferably comprises pre-locking the strain relief around the electrical power cord, wherein the strain relief in the pre-locked configuration is able to move laterally about the electrical power cord. Pressing the top mold block onto the bottom mold block preferably further comprising pressing the strain relief into a locked configuration, wherein the strain relief is securely engaged to the electrical power cord in the locked configuration. Pressing the strain relief into a locked configuration preferably comprises engaging one portion of the strain relief into a second portion of the strain relief in a direction perpendicular to length of the electrical power cord.

Pressing the strain relief into a locked configuration preferably comprises engaging one portion of the strain relief into a second portion of the strain relief in a direction parallel to length of the electrical power cord. The protrusions of the strain relief are preferably contoured having a first and a second beveled surface forming a ridge distal to the electrical power cord, and the mold cavity is preferably shaped to receive the protrusions of the strain relief and form a contact with the first and the second beveled surfaces, wherein when the top mold block is pressed toward the second mold block, the section of the mold cavity mold cavity adjacent to the first and second beveled surfaces urge the strain relief to move laterally along the electrical power cord to a desired location. The protrusions of the strain relief are preferably contoured having a first and a second beveled surface forming a ridge distal to the electrical power cord, and the mold cavity is shaped to receive the protrusions of the strain relief and form a contact with the first and the second beveled surfaces, wherein when the top mold block is pressed toward the second mold block, the section of the mold cavity mold cavity adjacent to the first and second beveled surfaces urge the strain relief to move along the electrical power cord to a desired angular orientation. The inner body assembly preferably further comprises one or more inner body protrusions projecting outward and away from the top of the inner body assembly, and the upper mold block is shaped to receive the inner body protrusions and form a seal surrounding the inner body protrusions to prevent the molten material from depositing on the top surface of the inner body protrusions. The inner body protrusions preferably indicate orientation.

In an eighth aspect, a method for manufacturing an overmolded electric plug with integrated strain relief is disclosed. The method comprises producing an inner body assembly comprising a wire assembly and an inner body, the wire assembly comprising an electrical power cord and electrical connectors, the inner body securing the electrical connectors, placing a strain relief around the electrical power cord, the strain relief having plurality of protrusions extending radially away from the electrical power cord, the strain relief having a coupling member extending away from the strain relief, and

6

connecting the coupling member of the strain relief to the inner body assembly. The method further comprises producing an injection mold comprising a top mold block, a bottom mold block, and a socket mold block, the injection mold having a mold cavity shaped to correspond to the desired shape of the overmolded electric plug with integrated strain relief, the bottom mold block shaped to receive and detachably secure an inner body assembly and a strain relief, the socket mold block having socket connectors configured to receive the electrical connectors, the injection mold having a feeder injection port. The method further comprises coupling the electrical connectors to the socket connectors of the socket mold block, placing the inner body assembly and the strain relief into the bottom mold, and pressing the top mold block onto the bottom mold block. The method further comprises injecting a molten insulating material into the injection mold through the feeder injection port, the injected molten material urging the air within the mold to vent via the multiple air escape paths, and removing the overmolded electric plug from the mold.

In an eighth preferred embodiment, the strain relief has an outer surface having a plurality of protrusions, and the mold cavity is shaped to receive the protrusions of the strain relief and form a seal surrounding the protrusions of the strain relief to prevent the molten material from depositing on the outer surface of the protrusions of the strain relief. Placing a strain relief around the electrical power cord preferably comprises pre-locking the strain relief around the electrical power cord. Pressing the top mold block onto the bottom mold block preferably further comprising pressing the strain relief into a locked configuration, wherein the strain relief is securely engaged to the electrical power cord in the locked configuration. Pressing the strain relief into a locked configuration preferably comprises engaging one portion of the strain relief into a second portion of the strain relief in a direction perpendicular to length of the electrical power cord. Pressing the strain relief into a locked configuration preferably comprises engaging one portion of the strain relief into a second portion of the strain relief in a direction parallel to length of the electrical power cord. The inner body assembly preferably further comprises one or more inner body protrusions projecting outward and away from the top of the inner body assembly, and the upper mold block is shaped to receive the inner body protrusions and form a seal surrounding the inner body protrusions to prevent the molten material from depositing on the top surface of the inner body protrusions. The inner body protrusions preferably indicate orientation.

In a ninth aspect, an injection mold system is disclosed. The injection mold system comprises a top mold block having a top mold cavity shaped to correspond to the desired shape of the upper portion of an overmolded electric plug, a bottom mold block having a bottom mold cavity shaped to correspond to the desired shape of the bottom portion of the overmolded electric plug, the bottom mold block shaped to receive and detachably secure an inner body assembly having protruding electrical prongs, a socket mold block having socket connectors configured to receive the electrical prongs, and a feeder injection port. The top and bottom mold cavities are locally contoured to engage protrusions of a pre-locked strain relief and place the strain relief into a locked configuration, wherein the strain relief in the pre-locked configuration is able to move laterally about the electrical power cord, the strain relief in the locked configuration is secured to the electrical power cord.

In a ninth preferred embodiment, the upper mold block further comprises recesses configured for receiving protrusions on a strain relief and forming seals surrounding the

strain relief protrusions to prevent the molten material from depositing on the top surface of the strain relief protrusions.

These and other features and advantages of the invention will become more apparent with a description of preferred embodiments in reference to the associated drawings.

#### DESCRIPTION OF THE DRAWINGS

FIG. 1 is a top, perspective view of an electrical plug with integrated strain relief.

FIG. 2 is a top, exploded view of a strain relief in an embodiment.

FIG. 3 is a top, perspective view of an assembled strain relief in an embodiment.

FIG. 4 is a top, perspective view of the strain relief depicted in FIGS. 2 and 3 having an overmolded housing.

FIG. 5 is a side view of strain relief surrounding an electrical power cord.

FIG. 6 is a schematic illustration of the strain relief urged to a desired location as a result of the contoured tooling engaging with the bevels of the protrusions of the strain relief.

FIG. 7 is a schematic illustration of the tooling placing and locking in place the strain relief to the proper position on the electrical power cord.

FIG. 8 is a side view of the overmolded strain relief.

FIG. 9 is a front, perspective view of a one-piece strain relief in an embodiment.

FIG. 10 is a side, perspective view of the strain relief in a pre-locked configuration.

FIG. 11 is a front view of the strain relief in a locked configuration.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The following preferred embodiments are directed to strain relief and electrical plugs with integrated strain relief. Other preferred embodiments are directed to the methods and systems for manufacturing electrical plugs with integrated strain relief.

Many electrical plugs are employed in applications where the electrical plugs are plugged-in and are unplugged frequently throughout the lifetime of an electrical tool or device. Ideally, users should unplug a device by firmly grasping and pulling the electrical plug from the socket. However, many users instead grasp and pull the electrical power cord. Unless the electrical plug incorporates strain relief, these plugs may fail as a user may inadvertently tear out the electrical wires from the plug. Moreover, many users may be uncertain if an electrical plug incorporates strain relief, and may select electrical power cords unsuitable for heavy-duty applications.

One or more embodiments provide a strain relief which is secured to an electrical power cord. The strain relief may comprise two sections which mate to form the strain relief. Other preferred embodiments may comprise a single one-piece body with multiple sections. One or more preferred embodiments employ a ratcheting mechanism which permanently secures the strain relief on the electrical power cord. The strain relief may be partially assembled in a pre-locked configuration on the electrical power cord where the strain relief may be positioned on the power cord, and then be further pressed to a locked configuration in which the is securely attached to the power cord.

In a preferred embodiment, the strain relief may have multiple protrusions extending radially away from the length of the electrical power cord. After the strain relief is overmolded with an overmold material, the outer surfaces of the protrusion are exposed and are visible to users. In a preferred embodiment, the protrusions have a different color than that of the overmold material. The shape and design of the protrusions may vary.

In a preferred embodiment, the shape of the protrusions enables the strain relief to be automatically centered and aligned on the electrical power cord during the manufacturing process. In an embodiment, the protrusions of the strain relief are contoured to form angled bevels leading to a distal ridge. The tooling which locks the strain relief is also countered. When the tooling proceeds to lock the strain relief, the contours of the tooling will urge the strain relief to move to the proper position on the electrical power cord. The tooling then presses the ratcheting mechanism of the pre-locked strain relief and acts to lock the strain relief in place.

In one or more embodiments, the electrical plug may have an inner body assembly which holds the electrical prongs. The inner body may be essentially encapsulated in an overmolding process. In an embodiment, the strain relief may have an "arm" or a coupling member which connects the strain relief to an inner body of the plug. The strain relief and the inner body may then be overmolded to have a protective overmold housing encapsulating most of the inner body and strain relief. Hence, should a user pull the electrical power cord to unplug an electrical plug, the strain relief secures the jacket of the power cord to the inner wires, and transfers the force to the inner body through the coupling member of the strain relief.

In one or more embodiments, the strain relief may provide strain relief through the overmold material. Should a user pull the electrical power cord to unplug an electrical plug, the strain relief secures the jacket of the power cord to the inner wires, and transfers the force to the inner body through the overmold material.

Teachings related to electrical plugs employing inner bodies and the manufacture thereof are discussed in U.S. application Ser. Nos. 14/197,744, 14/198,185, 14/198,199, filed Mar. 5, 2014 each entitled "INSULATING ELECTRICAL PLUGS AND METHOD OF MANUFACTURE," the disclosures of which are incorporated herein by reference in their entirety.

As used herein and as is commonly known in the art, electric plugs are connectors which engage with electrical sockets to transmit electrical current and power. While embodiments discussed herein refer to plugs generally conforming to United States and North American 120 volt standards, plugs conforming to other standards, other voltages, direct current, and multiple phase applications are contemplated in one or more embodiments. While embodiments discussed below may describe flat plug, it shall be understood that the general discussion of flat plugs and straight plugs, and the manufacture thereof generally apply to both configurations.

In one or more embodiments, a cylindrical coordinate system may be employed to describe the relative configuration of the components. Reference to a cylindrical or longitudinal axis may refer generally to the axis defined by the length of the electrical power cord immediately surrounding the plug and strain relief. The distance from the longitudinal axis may be described as the radial distance or radius. Reference to the term "radially away" refers to directions perpendicular to the longitudinal axis.

In one or more embodiments, the overmold material may be Polyvinyl Chloride ("PVC"), thermoplastics, soft plastics, polymers, or other materials for example. The strain relief and the plug inner body may be fabricated with plastics, polymers, and other materials for example. In one or more embodiments, the material of the strain relief and the plug inner body may be sufficiently pliable so that components deform or flex to enable components to snap into place for various forms of ratcheting mechanisms.

FIG. 1 is a top, perspective view of an electrical plug with integrated strain relief 101. The plug with integrated strain relief 101 comprises a plug section 120, a strain relief section 140, and an electrical power cord 160. The plug section 120 comprises an overmolded inner body (discussed below) securing the electrical prongs 102 and 104 in place. The inner body has protrusions 110 and 112 which extend through the overmold material 106 and are visible. The strain relief section 140 has an inner strain relief (discussed below) that surrounds and secures the electrical power cord 160. The inner strain relief has protrusions 135 which extend through the overmold material 136 which are visible. In an embodiment, the strain relief may have multiple protrusions having a length parallel with the length of the electrical power cord 160. The strain relief section is physically connected to the electrical plug section 120 through the overmold sections 126 in an embodiment. Other coupling mechanisms are discussed below in greater detail. The electrical plug protrusions 110 and 112 and the strain relief protrusions 135 may have a color different from the surrounding overmold material and serve as visible evidence that the electrical plug 101 has an integrated strain relief for heavy-duty applications. In one or

## 11

more embodiments, the protrusions **110**, **112**, and **135** may be yellow, red, blue, or orange, while the overmold material **106**, **126**, and **136** may be darker.

FIGS. 2-4 illustrate the composition and assembly of a strain relief **201** in one or more embodiments. A cylindrical coordinate system may be employed to describe the relative configuration of the components. The cylindrical or longitudinal axis **204** may refer generally to the axis defined by the length of the electrical power cord **160** immediately surrounding the plug and strain relief as shown in FIG. 4. The distance away from the longitudinal axis may be described as the radial distance or radius. Reference to the term “radially away” refers to directions perpendicular to the longitudinal axis such as axis **208** shown in FIG. 2. The passageway **206** is the internal space through which an electrical power cord **160** will be placed.

The strain relief **201** is comprised of two sections with a first half-shell **212** having a plurality of posts **214** extending from the first section **212** in a direction parallel with axis **208** (i.e., a direction perpendicular to the length of the electrical power cord **160** immediately surrounding the strain relief **201**). The second half-shell **210** has a plurality of holes **220** where each of the holes **220** are formed to receive and secure the corresponding post **214** during an assembly process. Each of the posts **214** has multiple rings **215** along the length of the post **214**. The rings **215** on the posts **214** may act as a ratcheting mechanism where posts **214** may be readily inserted into the holes **220**, but the shape of the posts **214** and holes **220** may prevent the posts **214** from being removed from the holes **220**. The strain relief **201** has an inner clamping surface **202** and an outer surface **218**, where the inner clamping surface **202** is configured to form a passageway **206** having a longitudinal axis **204** for surrounding and securing an electrical power cord **160**. As shown in FIG. 2, the strain relief **201** may be manually positioned around the electrical power cord **160** in a pre-locked configuration where the first and second half-shells **210** and **212** do not readily separate but are not fully engaged to secure the electrical power cord **160**. As shown in FIG. 3, once the strain relief **201** is properly positioned, the first and second half-shells **210** and **212** may be fully engaged to a locked position where the strain relief **201** securely engages the electrical power cord **160**.

The outer surface **218** has a plurality of protrusions **216** extending radially away from the longitudinal axis **204**. In an embodiment, the strain relief **201** has two protrusions on opposite sides having a length perpendicular to the length of the electrical power cord **160**. FIG. 4 shows the overmold strain relief **251** having an overmold housing **260** partially surrounding the strain relief clamp **201**, where the outer surfaces of the protrusions **216** of the strain relief extends to or beyond the outer surface of the overmold housing **260**, and is visible to a user.

FIGS. 5-8 illustrate features of the strain relief which provide lateral and orientation self-placement during an assembly process. As seen in FIGS. 5 and 6, the protrusions **216** of the strain relief **201** as well as the top and bottom mold blocks **280** and **282** are contoured to facilitate self-alignment of the strain relief **201** within the top and bottom mold blocks **280** and **282**.

As seen in FIG. 5, the protrusions **216** are contoured to have a first beveled surface **230** and a second beveled surface **234** forming a ridge **232** distal to the longitudinal axis **204**. In an embodiment, the first and the second beveled surfaces **230** and **234** are on opposite sides of the strain relief **201**. The lower protrusion **216** is also contoured to have a first beveled surface **236** and a second beveled surface **240** forming a ridge **238** distal to the longitudinal axis **204**. In one or more

## 12

embodiments, the ridges **232** and **238** may form a line, or the ridges **232** and **238** may form a plateau. In one or more embodiments, the beveled surfaces **230**, **234**, **236**, and **240** may be generally flat, or they may have a curvature. In an embodiment, the top mold block **280** is contoured to have a first and a second beveled surface **250** and **254** leading to a surface **252** distal to the longitudinal axis **204**. The bottom mold block **282** is contoured to have a third and a fourth beveled surface **256** and **262** leading to a surface **258** distal to the longitudinal axis **204**.

The assembly process begins by placing the strain relief **201** on the electrical power cord **160** in a pre-locked configuration. In a pre-locked configuration, the first half-shell **210** and the second half-shell **212** are not fully mated so that a gap **290** allows the strain relief **201** to move laterally on the electrical power cable **160**. As the top and bottom mold blocks **280** and **282** begin to close, the surfaces **250**, **252**, and **254** of the top mold block engage **280** with the beveled surfaces **230** and **234** and the ridge **232** of the top protrusion **216**, and the surfaces **256**, **258** and **262** of the bottom mold block **282** engage with the beveled surfaces **236** and **240** and the ridge **238** of the bottom protrusion **216**. The vertical forces **253** and **259** exert lateral forces **281** onto the strain relief **201**, which moves the strain relief **201** to the correct lateral position and orientation. Once the strain relief **201** moves to the correct location shown in FIG. 7, all of the beveled surfaces of the protrusions **230**, **234**, **236**, and **240** as well as the ridges **232** and **238** are in contact with the top and bottom mold blocks **280** and **282** which removes the net lateral force **281** and vertically presses the strain relief **201** into a locked position.

As illustrated in FIG. 7, once the top mold block **280** is seated on the bottom mold blocks **282**, overmold material **292** is injected into the formed cavity. The mold cavity formed by the surfaces **250** and **254** of the top mold block **280** and the surfaces **256** and **262** of the bottom mold block **282** is shaped to receive the protrusions **216** of the strain relief **201** and form a seal surrounding the bevels **230**, **234**, **236**, and **240** of the protrusions **216** of the strain relief **201** to prevent the molten insulating material from depositing on the outer surfaces **230**, **234**, **236**, and **240** of the protrusions **216**. After the overmold material sets, the top and bottom mold blocks **280** and **282** are separated rendering the overmolded strain relief shown in FIG. 8.

FIGS. 9-12 depict a one-piece strain relief **301** having a first section **310** and a second section **312**. The strain relief **301** has an inner clamping surface **302** and an outer surface **318**, where the inner clamping surface **302** is configured to form a passageway **306** having a longitudinal axis **304** (i.e., parallel with the length of the electrical power cord **160** immediately surrounding the strain relief **301**) for surrounding and securing an electrical power cord **160**. The outer surface **318** has a plurality of protrusions **316** extending radially away from the longitudinal axis **304**. In an embodiment, the outer surface **318** has multiple protrusions **316** having a length parallel with the longitudinal axis **304**.

The first section **310** is hingably connected to the second section **312** such that the first section **310** is configured to rotate relative to the second section **312** about the longitudinal axis **304** (i.e., the length of the electrical cord immediately surrounding the strain relief **301**). The first section **310** couples to the second section **312** via flexible member **309**. As such, the flexible member **309** hingably couples the first and second sections **310** and **312** because the flexible member **309** acts as a hinge which allows the first section **310** and the second section **312** to rotate about the longitudinal axis **304**. The flexible member **309** may be thinner or may be made more flexible so that the flexible member **309** acts as a hinge.

13

The first section 310 engages with the second section 312 through a latching mechanism 313. The first section 310 has a tab 311 having a pawl 315. The second section 312 has a first notch 317 and a second notch 319. The pawl 315 is a protruding finger which engages with the notches 317 and 319. The pawl 315 and the notches 317 and 319 are shaped to allow the pawl 315 to move from notch 317 to 319 with moderate force to flex the material of the strain relief 301. However, the asymmetrical shape of the pawl 315 and the notches 317 and 319 prevent the pawl 315 from easily moving from notch 319 to notch 317.

During assembly, the pawl 315 snaps into notch 317 to form a pre-lock configuration where the first and second sections 310 and 312 are engaged, but the strain relief 301 would not fully engage with an electrical power cord 160. The first section 310 may be further pressed into the second section 312 such that the pawl 315 snaps into the second notch 319 to form the locked configuration such that the strain relief 301 would securely engage with an electrical power cord 160. FIG. 11 is a front view of the strain relief 301 in a locked configuration.

In one or more embodiments, the clamping surface such as clamping surface 304 may be modified to more fully secure the strain relief to an electrical power cord. For example, FIG. 12 is a front view of a strain relief 321 having ridges 322 on the inner surface of the strain relief. The ridges 322 may grip into and securely engages the electrical power cord 160.

FIGS. 13-15 illustrate key features of an overmolded strain relief 332. Strain relief 331 is shown positioned and secured to the electrical power cord 160. In one or more embodiments, the strain relief 331 has a similar latching mechanism 313 as discussed above with respect to strain relief 301 in FIGS. 9-10. FIG. 14 illustrates the internal details of the strain relief 331 partially encapsulated with the overmold housing 335. As seen in FIG. 15, the protrusions 333 are visible in the overmold housing 335.

FIGS. 16-18 depict a one-piece strain relief 341 having a first section 340 and a second section 342. The strain relief 341 has an inner clamping surface 352 and an outer surface 347, where the inner clamping surface 352 is configured to encircle a longitudinal axis 344 for surrounding and securing an electrical power cord 160. The inner clamping surface 352 has a plurality of ridges 353 for engaging with an electrical power cord 160. The outer surface 347 has a plurality of protrusions 346 extending radially away from the longitudinal axis 344.

The first section 340 is hingably connected to the second section 342 such that the first section 340 is configured to rotate relative to the second section 342 about the longitudinal axis 344 (i.e., the length of the electrical power cord 160). The first section 340 couples to the second section 342 via flexible member 345.

The first section 340 engages with the second section 342 through a latching mechanism 343. The first section 340 has a pawl 348, and the second section 342 has a notch 350. When the first section 340 is engaging with the second section 342, the pawl 348 snaps into notch 350 to form a locked configuration where the first and second sections 340 and 342 are engaged to secure an electrical power cord 160. Additional notches in the second section 342 are contemplated in one or more embodiments.

FIGS. 19-21 depict a two-piece strain relief 401 having a first section 410 and a second section 412 having an essentially "U" shaped half-shell. The strain relief 401 has inner clamping surfaces 402a and 402b on the first and second sections 410 and 412 respectively. The strain relief 401 has outer surface 419a and 419b on the first and second sections

14

410 and 412 respectively, where the inner clamping surfaces 402a and 402b are configured to form a passageway 411 having a longitudinal axis 404 for surrounding and securing an electrical power cord 160. The outer surfaces 419a and 419b have a plurality of protrusions 416 extending radially away from the longitudinal axis 404.

The first section 410 has two pawls 448 extending away from the first section 410. The second section 412 has two racks 418 of teeth 406a-406c, where each rack 418 of teeth 406a-406c is configured to receive the corresponding pawl 448 from the first section 410 during an assembly process. As the first section 410 is urged downward to the second section 412, the pawls 448 first engage with teeth 406a, and then with teeth 406b in the pre-lock configurations. As the first section is further urged downward, the pawls 448 engage with teeth 406c to form the locked configuration. FIG. 21 depicts the overmolded strain relief 421 comprising the strain relief 401 and the overmold housing 422. The protrusions 416 are visible in the overmolded strain relief 421. In an embodiment, the strain relief 341 has two protrusions 346 on opposite sides having a length perpendicular with the length of the electrical power cord 160.

FIGS. 22-24 depict a two-piece strain relief 451 having a first section 460 and a second section 462 shaped essentially as half-shells. The strain relief 451 has inner clamping surfaces 452a and 452b on the first and second sections 460 and 462 respectively. The strain relief 451 has outer surface 458a and 458b on the first and second sections 460 and 462 respectively, where the inner clamping surfaces 452a and 452b are configured to encircle a longitudinal axis 454 for surrounding and securing an electrical power cord 160. The outer surfaces 458a and 458b have a plurality of protrusions 456 extending radially away from the longitudinal axis 404. In an embodiment, the strain relief 451 has two protrusions 456 on opposite sides having a length perpendicular with the length of the electrical power cord 160.

The first section 460 has a first and a second rack 470a and 470b and a first and a second guide arm 472a and 472b extending away from the first section 460. The second section has a third and a fourth rack 476a and 476b a third and fourth guide arms 474a and 474b extending away from the second section 462. The third and fourth racks 476a and 476b are configured to receive the first and second racks 470a and 470b during an assembly process. As illustrated in FIG. 23, the guide arms 472a, 472b, 474a, and 474b serve to keep the racks 470a and 476a adjacent and 470b and 474b adjacent after assembly.

FIGS. 25-27 depict a two-piece strain relief 501 having a first section 510 and a second section 512 shaped essentially as half-shells. The strain relief 501 has an inner clamping surface 502 and an outer surface 518, where the inner clamping surface 502 is configured to encircle a longitudinal axis 504 for surrounding and securing an electrical power cord 160. The outer surface 518 has a plurality of protrusions 516 extending radially away from the longitudinal axis 344. In an embodiment, the strain relief 501 has multiple protrusions 516 having a length parallel with the length of electrical power cord 160.

The first section 510 engages with the second section 512 through a latching mechanisms 543a and 543b. The first section 510 has pawls 540a and 540b, and the second section 512 has notches 530a-530c and 531a-531c. When the first section 510 is engaging with the second section 512, the pawl 540a snaps into notch 530a and the pawl 540b snaps into notch 531a for the pre-locked configuration. As the first section 510 is pressed further into the second section 512, the pawl 540a snaps into notch 530c, and pawl 540b snaps into

15

notch 531c for the locked configuration. As seen in FIG. 27, the protrusions 516 extend through the overmold housing 511 and are visible to the user.

FIGS. 28-30 depict a two-piece strain relief 551 having a first generally cylindrical section 550 and a second generally cylindrical section 552, each having protrusions 566. The first section 550 has a pawl 556 extending away, and the second section has a set of teeth 554a, 554b, and 554c configured for mating with the pawl 556. The teeth 554a-554c have a length perpendicular to the longitudinal axis 553 (i.e., the direction of the length of the electrical power cord). The first section 550 mates with the second section 552 by moving in a direction parallel with the longitudinal axis 553. The multiple teeth 554a-554c enable the first and second sections 550 and 552 to engage in pre-locked and locked configurations. FIG. 30 illustrates that the protrusions 566 are visible through the overmold housing 560.

FIG. 31 illustrates a two-piece strain relief 601 having a first section 610 and a second section 612. The strain relief 601 has a plurality of protrusions 616 extending radially away from the longitudinal axis 604. The first section has an annular pawl 608, and the second section has a series of recesses 606a-606c configured to receive and mate with the pawl 608 during an assembly process. The first section 610 mates with the second section 612 by moving in a direction parallel with the longitudinal axis 604 (i.e., the direction of the length of the electrical power cord). The multiple teeth 606a-606c enable the first and second sections 610 and 612 to engage in a pre-locked and a locked configuration.

FIG. 32 illustrates the self-aligning feature of the strain relief 601 placed into an injection mold having top and bottom mold blocks 680 and 682. The top mold blocks have bevels 650 and 652, and the bottom mold block has beveled surface 654 and 656. When the vertical forces 666 act to close the top mold block 680 onto the bottom mold block 682, the beveled surfaces 650, 652, 654, and 656 engage with the beveled protrusions 616 and cause lateral forces 662 and 664 to position the strain relief 601 into the correct position and orientation. Once the strain relief 601 is in the proper position, the lateral forces 662 and 664 act to place the strain relief 601 into a locked configuration.

FIGS. 33-44 illustrate the assembly and process for manufacturing an electrical plug with integrated strain relief 101 in one or more embodiments. FIG. 33 is a top, perspective view of an inner body assembly 701 comprising a wire assembly 710 and a one-piece inner body 740. The wire assembly 710 comprising an electrical power cord 160 having at least two wires 712 and 714 enclosed within an insulating cable jacket 716. The wire assembly further comprising at least two electrical connectors 718 and 720 each electrical connector having an electrical prong 722 and 724, the electrical connectors connected to a corresponding wire forming at least two electric power lines. The inner body 740 secures and essentially surrounds the electrical connectors 718 and 720 and a portion of the wire proximal to the electrical connectors. The one-piece inner body 740 comprises a base 750 having one or more latching mechanisms 751 and 752, a first cover 753 hingably coupled to the base 750 on a first side of the base 750, and a second cover 754 hingably coupled to the base 750 on a second side of the base 750, the second side of the base opposite that of the first side of the base.

FIG. 34 is a top, perspective view of the inner body assembly 701 and a strain relief 730. The inner body 740 has one or more inner body protrusions 755 and 756 projecting outward and away from the inner body 740. In an embodiment, the inner body protrusions 755 and 756 are shaped to indicate an orientation. The strain relief 730 has several protrusions 731

16

with beveled surfaces 732. As seen in FIG. 35, the strain relief 730 comprises a one-piece body having first section 734 and a second section 736. The first section 734 engages with the second section 736 through a latching mechanism 738. The first section 734 has a tab 739 with pawl 740. The second section 736 has a first notch 741 and a second notch 742. As depicted in FIG. 35, the first section 734 is engaging with the second section 736, and the pawl 740 snaps into notch 741 to form a pre-lock configuration where the first and second sections 734 and 736 are engaged, but would not fully engage with an electrical power cord 160.

FIG. 36 is an exploded view of an injection mold 801 comprising a top mold block 850, a bottom mold block 810, and a socket mold block 880. The injection mold 801 has a mold cavity having a top mold cavity 852 in the top mold block 850 and a bottom mold cavity 812 in the bottom mold block 810 shaped to correspond to the desired shape of the overmolded electric plug with integrated strain relief 101. The bottom mold block 810 shaped to receive and detachably secure an inner body assembly 701 and a strain relief clam 730. The socket mold block 880 has first and second female connectors 884 and 882 for receiving the electrical prongs 724 and 722 of the inner wire assembly 701. The injection mold 801 has a feeder injection port 820.

As seen in FIG. 37, the wire assembly 701 is plugged into the female connectors 882 and 884. The wire assembly 701 is then seated into the bottom mold block as shown in FIG. 38.

FIG. 39 is a cross-sectional view of the assembly shown in FIG. 38 and illustrates features of the strain relief 730 which provide lateral and orientation self-placement during an assembly process. The protrusions 732 of the strain relief 730 as well as the top and bottom mold blocks 850 and 810 are contoured to facilitate self-alignment of the strain relief 730 within the top and bottom mold blocks 850 and 810.

Specifically, the protrusions 732 are contoured to have a first beveled surface 736 and a second beveled surface 238 forming a ridge 737 distal to the longitudinal axis 704. In one or more embodiments, the beveled surfaces 736 and 738 may be generally flat, or they may have a curvature. In an embodiment, the top mold block 850 is contoured to have a locally contoured surface 860 and the bottom mold block 810 is contoured to have a contoured surface 830. When the top and bottom mold blocks 850 and 810 begin to close, the contoured surfaces 860 and 830 engage with the beveled surfaces 736 and 738 of the strain relief protrusions 732, the vertical force 870 is translated into lateral force 872 which shifts the strain relief 730 to the right in this example, moving from position 734 to 862. FIG. 40 presents a cross-section view of the relative positions of the strain relief 730 and the injection mold 801.

FIG. 41 illustrates the key features of the orientation self-placement of the injection mold 801. The strain relief 730 is positioned on the bottom mold block but has an orientation angle  $\theta$  relative to the vertical direction. When the top and bottom mold blocks 850 and 810 begin to close, the contoured surfaces 860 and 830 engage with the beveled surfaces 736 and 738 of the strain relief protrusions 732, the vertical force 870 is translated into lateral force 872 which shifts the strain relief 730 to the vertical position as depicted by FIG. 42.

FIG. 43 shows the assembled injection mold 801. Overmold material is injected into the injection mold feeder injection port 820. The mold cavity is shaped to receive the protrusions of the strain relief and form a seal surrounding the protrusions of the strain relief to prevent the molten material from depositing on the outer surface of the protrusions of the strain relief. As shown in FIG. 44, the top, bottom, and socket

17

mold blocks **850**, **810**, and **880** are separated, and the overmolded electrical plug with integrated strain relief **101** is removed.

FIGS. **45-53** illustrate the assembly and process for manufacturing an electrical plug with integrated strain relief employing an internal coupling mechanism in one or more embodiments. FIG. **45** is a top, perspective view of an inner body **940**, a coupling member **980**, and a strain relief **930**. In one or more embodiments, the coupling member **980** is integral with the strain relief **930**. The coupling member **980** has a clip **982**, and the inner body **940** has rails **942** which are configured to receive and couple with the clip **982** as shown in FIG. **46**. The one-piece inner body **940** comprises a base **950** having one or more latching mechanisms **951** and **952**, a first cover **953** hingably coupled to the base **950** on a first side of the base **950**, and a second cover **954** hingably coupled to the base **950** on a second side of the base **950**, the second side of the base opposite that of the first side of the base.

As depicted in FIG. **47**, the wire assembly is placed in the inner body **940** to form an inner body assembly **901**. The electrical power cord **160** of the inner body assembly **901** is placed in the strain relief **930**. The wire assembly **910** comprises an electrical power cord **160** having at least two wires **712** and **714** enclosed within an insulating cable jacket **716**. The wire assembly further comprising at least two electrical connectors **718** and **720** each electrical connector having an electrical prong **722** and **724**, the electrical connectors connected to a corresponding wire forming at least two electric power lines. The inner body **940** secures and essentially surrounds the electrical connectors and a portion of the wire proximal to the electrical connectors.

Referring to FIGS. **48** and **49**, the two sections of the strain relief **930** are coupled together as discussed above, and placed in pre-locked position around the electrical power cord **160**. The strain relief **930** has several protrusions **932**. The inner body **940** has one or more inner body protrusions **954** and **955** projecting outward and away from the inner body **940**. In an embodiment, the inner body protrusions **954** and **955** are shaped to indicate an orientation.

FIG. **50** is an exploded view of an injection mold **1001** comprising a top mold block **1050**, a bottom mold block **1010**, and a socket mold block **1080**. The injection mold **1001** has a mold cavity having a top mold cavity **1052** in the top mold block **1050** and a bottom mold cavity **1012** in the bottom mold block **1010** shaped to correspond to the desired shape of the overmolded electric plug with integrated strain relief **1101** as shown in FIG. **53**. The bottom mold block **1010** shaped to receive and detachably secure an inner body assembly **901** and a strain relief clam **930**. The socket mold block **880** has first and second female connectors **1084** and **1082** for receiving the electrical prongs **724** and **722** of the inner wire assembly **901**.

Referring to FIG. **51**, the electrical prongs **724** and **722** are plugged into the female connectors **1084** and **1082**. The inner body assembly **901** and the strain relief are placed into the bottom mold block **1010**. As depicted in FIG. **52**, the top mold block **1050** is placed over the bottom mold block **1010**, and overmold material is injected into the injection mold feeder injection port **1020**. As shown in FIG. **53**, the top, bottom, and socket mold blocks **1050**, **1010**, and **1080** are separated, and the overmolded electrical plug with integrated strain relief **1101** is removed.

FIG. **54** presents an exemplary process **1201** for manufacturing an overmolded electrical plug with integrated strain relief **101**. The process begins at step **1202**. An inner electrical plug body assembly having an electrical power cord is provided (step **1204**). A strain relief is pre-locked around the

18

electrical power cord (step **1206**). An injection mold comprising a top and bottom mold block is produced (step **1208**). The inner body assembly and the strain relief are placed into the injection mold (step **1210**). The top mold block is pressed onto the bottom mold block (step **1212**). The strain relief is positioned and orientated as a result of pressing the top mold block onto the bottom mold block (step **1214**). A molten insulating material is injected into the injection mold (step **1216**). The overmolded electric plug with integrated strain relief is removed from the mold (step **1218**) and the process ends (steps **1220**).

FIG. **55** presents an exemplary process **1301** for manufacturing an overmolded electrical plug with integrated strain relief **1101**. The process begins at **1302**. An inner electrical plug body assembly having an electrical power cord is provided (step **1304**). A strain relief is attached to the inner electrical plug assembly (step **1306**). A strain relief is pre-locked around the electrical power cord (step **1308**). An injection mold comprising a top and bottom mold block is produced (step **1310**). The inner body assembly and the strain relief are placed into the injection mold (step **1312**). The top mold block is pressed onto the bottom mold block (step **1314**). A molten insulating material is injected into the injection mold (step **1316**). The overmolded electric plug with integrated strain relief is removed from the mold (step **1318**), and the process ends (step **1320**).

Although the invention has been discussed with reference to specific embodiments, it is apparent and should be understood that the concept can be otherwise embodied to achieve the advantages discussed. The preferred embodiments above have been described primarily as electrical plugs with integrated strain relief. In this regard, the foregoing description of the electrical plugs with integrated strain relief is presented for purposes of illustration and description. Furthermore, the description is not intended to limit the invention to the form disclosed herein. Accordingly, variants and modifications consistent with the following teachings, skill, and knowledge of the relevant art, are within the scope of the present invention. The embodiments described herein are further intended to explain modes known for practicing the invention disclosed herewith and to enable others skilled in the art to utilize the invention in equivalent, or alternative embodiments and with various modifications considered necessary by the particular application(s) or use(s) of the present invention.

What is claimed is:

1. A strain relief assembly for an electrical power cord, comprising:

- a strain relief having an inner clamping surface and an outer surface, the inner clamping surface configured to form a passageway for surrounding and securing an electrical power cord, the outer surface having a plurality of protrusions extending radially away from the passageway; and
- an overmold housing molded over at least a portion of the strain relief,
- wherein the protrusions of the strain relief radially extend to or beyond the outer surface of the overmold housing, and
- wherein the outer surfaces of the protrusions are not covered by the overmold housing such that the outer surfaces of the protrusions are externally visible.

2. The strain relief assembly for an electrical power cord of claim 1, wherein the protrusions are contoured to enable lateral positioning on an electrical power cord during the overmold process.

3. The strain relief assembly for an electrical power cord of claim 1, wherein:

19

the strain relief has a pre-locked configuration and a locked configuration;

the strain relief in the pre-locked configuration is able to move laterally about an electrical power cord; and  
the strain relief in the locked configuration is permanently secured to the electrical power cord.

4. The strain relief assembly for an electrical power cord of claim 1, wherein the strain relief comprises a first section and a second section, and wherein the first section and the section are configured to be locked together.

5. The strain relief assembly for an electrical power cord of claim 4, wherein:

the first section comprises a first half-shell having one or more first set of protrusions, the first half-shell having a plurality of posts extending from the first half-shell,  
the second section comprises a second half-shell having one or more second set of protrusions, the second section having a plurality of holes, each of the holes formed to receive and secure the corresponding inserted post during an assembly process.

6. The strain relief assembly for an electrical power cord of claim 4, wherein:

the first section has one or more first set of protrusions, the first section having two pawls extending away from the first section; and

the second section comprises a second set of protrusions, the second section having two racks of teeth, wherein each rack of teeth are configured to receive the corresponding pawl from the first section during an assembly process.

7. The strain relief assembly for an electrical power cord of claim 4, wherein:

the first section having a first set of protrusions, the first section having a first and a second rack extending away from the first section; and,

the second section having a second set of protrusions, the second section having a third and a fourth rack extending away from the second section, wherein the third and fourth racks are configured to receive the first and second racks during an assembly process.

8. The strain relief assembly for an electrical power cord of claim 4, wherein:

the first section comprises a first generally cylindrical section having a first set of protrusions, the first generally cylindrical section having two pawls extending away from the first generally cylindrical section; and  
the second section comprises a second generally cylindrical section having one or more second set of protrusions, the second generally cylindrical section having two sets of teeth, wherein each set of teeth are configured to receive the corresponding pawl from the first generally cylindrical section during an assembly process.

9. The strain relief assembly for an electrical power cord of claim 1, wherein the strain relief comprises one-piece body having a first and a second section, the first section hingably connected to the second section, the first section configured to rotate relative to the second section about an axis parallel with the length of the electrical cord.

10. A strain relief assembly for an electrical power cord, comprising:

an electrical power cord;

a strain relief having an inner clamping surface and an outer surface, the inner clamping surface surrounding and securing the electrical power cord, the outer surface

20

having a plurality of protrusions extending radially away from the length of the electrical power cord; and  
an overmold housing molded over at least a portion of the strain relief, wherein the protrusions of the strain relief radially extends to or beyond the outer surface of the overmold housing,

wherein the outer surfaces of the protrusions are not covered by the overmold housing so as to be externally visible.

11. The strain relief assembly for an electrical power cord of claim 10, wherein the protrusions are contoured to enable lateral positioning on an electrical power cord during the overmold process.

12. The strain relief assembly for an electrical power cord of claim 10, wherein the strain relief has a pre-locked configuration and a locked configuration, wherein the strain relief in the pre-locked configuration is able to move laterally about an electrical power cord, the strain relief in the locked configuration is secured to the electrical power cord.

13. The strain relief assembly for an electrical power cord of claim 10, wherein the strain relief comprises a first section and a second section, and wherein the first section and the section are configured to be locked together.

14. The strain relief assembly for an electrical power cord of claim 13, wherein:

the first section comprises a first half-shell having one or more first set of protrusions, the first half-shell having a plurality of posts extending from the first half-shell,

the second section comprises a second half-shell having one or more second set of protrusions, the second section having a plurality of holes, each of the holes formed to receive and secure the corresponding post during an assembly process.

15. A strain relief assembly for an electrical power cord, comprising:

a strain relief having an inner clamping surface and an outer surface, the inner clamping surface configured to form a passageway for surrounding and securing an electrical power cord, the outer surface having a plurality of protrusions extending radially away from the passageway, the strain relief having a coupling member extending axially away from the strain relief and configured to connect with an electrical plug inner body; and,

an overmold housing molded over at least a portion of the strain relief, wherein the protrusions of the strain relief radially extends to or beyond the outer surface of the overmold housing,

wherein the outer surfaces of the protrusions are not covered by the overmold housing.

16. The strain relief assembly for an electrical power cord of claim 15, wherein the strain relief has a pre-locked configuration and a locked configuration, wherein the strain relief in the pre-locked configuration is able to move laterally about an electrical power cord, the strain relief in the locked configuration is permanently secured to the electrical power cord.

17. The strain relief assembly for an electrical power cord of claim 15, wherein the strain relief comprises one-piece body having a first section and a second section, the first section hingably connected to the second section, the first section configured to rotate relative to the second section about an axis parallel with the length of the electrical power cord, the first section configured to be locked to the second section.
